For additional information about steam tracing, please refer to the Steam Tracing Specification Guide (Thermon Form TSP0010U) or contact Thermon.

Introduction . . .

All too often an old steam tracing specification or previously adopted practices are followed which overlook new product developments or improvements. Today there are more types of steam tracers to choose from than ever before, providing a range of conductances to closely match the actual heat requirements for a given pipe heating system. By maximising performance with a range of steam tracers while minimising the total cost of unnecessary components, the cost of ownership for a steam tracing system is optimised.

This design guide addresses the steam tracing requirements of piping and equipment by matching the heating requirements with the type of steam tracer best suited for that application. The information contained in this design guide will take the reader through a step-by-step procedure to make proper steam tracer selections based on:

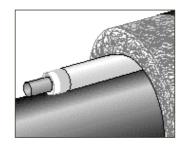

- Pipe size
- Thermal insulation type and thickness
- Desired maintain temperature range
- Maximum exposure temperature limitations
- · Minimum ambient temperature

After following the prescribed steps in this design guide, the reader will be able to design, select and/or specify or establish a bill of materials for a steam tracing system.

For applications ranging from freeze protecting water lines to maintaining elevated process temperatures as high as 677°C, Thermon has a tracing product to fit the application. These product families are distinctly broken down into three groups: isolated tracers, bare convection tracers and conduction tracers.

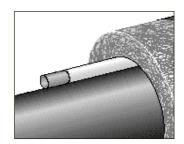

Isolated Tracers . . . Designed for use with low to medium-low heat requirements, Thermon's SafeTrace™ SLS-IT and DLS-IT are metallic tracer tubes covered with composite materials that lower thermal conductance to reduce heat output and temperature. The reduced heat output of SafeTrace SLS-IT and DLS-IT is predictable to ensure controlled heat distribution along the length of a traced pipe without hot spots or overheating. These tracers also utilise a safety yellow identification jacket to signify the presence of inherently dangerous

materials such as steam. A feature unique to SafeTrace SLS-IT and DLS-IT is their ability to run continuously from the steam supply manifold, along the pipe and to the condensate return manifold.

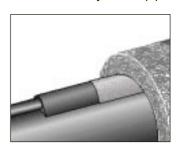

Convection Tracers... By using bare tracers or SafeTrace BTS tracers, convection tracing provides medium-low to medium heat transfer requirements. SafeTrace BTS is a metallic

tracer tube covered with a special high temperature polymer jacket that provides a measure of personnel burn protection without sacrificing thermal performance. The safety yellow jacket also provides corrosion resistance to most acids and alkalis.

Conduction Tracers . . . When the heat requirements exceed the capabilities of isolated and convection tracers, tracers aided by heat transfer compounds should be used. Thermon's heat transfer compounds, available in a wide variety of configurations to meet the application requirements, provide excellent heat transfer at a fraction of the cost of a jacketed pipe

system while eliminating the possibility of product contamination. The heat transfer properties of Thermon's compounds are so good that a single tracer utilising heat transfer compound will do the work of three to five bare tracers.

Computer-Aided Design Program . . .

Thermon has developed a sophisticated yet easy-to-use computer program, CompuTrace™, that provides detailed design and performance information. Users of CompuTrace are able to input application-specific information into the program and obtain detailed performance information. Calculations made within the program are based on universally accepted process heat transfer equations.

The information input to and/or generated from CompuTrace can be printed and summary reports, including "condensate load" information, exported for use in other programs. While CompuTrace is a valuable asset to use in designing a steam tracing system, the design steps detailed in this guide will still form the basis for identifying the design process necessary to establish a properly functioning steam tracing system.

Steam Tracing Design Outline . . .

The six steps below outline the design and selection process for a steam tracing system. The step-by-step procedures that follow the outline will provide the reader with the detailed information required to design, select and/or specify a fully functional steam tracing system.

Step 1: Establish Design Parameters

Collect relevant project data:

- a. Piping/equipment
 - Diameter Length
- b. Temperature
 - Low ambient
 - Maintain temperature
 - High temperature Limits/excursions
- c. Insulation
 - Type Thickness Oversized?
- d. Availability of steam
 - Pressure
 - Location

Step 2: Select the Proper Thermon Steam Tracing Method

Using information gathered in Step 1 and based on:

- a. General selection tables
- b. CompuTrace computer design program

Step 3: Identify Base Maintain Temperature

Using supplied tables and based on:

- a. Pipe size
- b. Insulation thickness
- c. Steam pressure
- d. Tracer type and quantity

Step 4: Apply Any Adjustment Factors

Based on:

- a. Different low ambient temperatures
- b. Different thermal insulation types

Step 5: Determine Steam Tracing Circuit Lengths

Based on:

- a. Steam pressure
- b. Quantity of tracers
- c. Tracer tubing diameter
- d. Adjustments for accumulated vertical tracer rise, elbows and bends

Step 6: Choose Options/Accessories

Based on:

- a. Tracer type
- b. Attachment method

Basis for a Good Design . . .

Every steam tracing design will involve six design factors of which three are given (fixed) and three are variable. The given factors are: nominal pipe size, desired maintain temperature and low ambient temperature. The variable factors are: tracer type, size and number; steam pressure (temperature); and insulation type and thickness. Establishing a balance amongst the variable factors will provide maintain temperatures within the desired range. Conversely, should any of the variable factors deviate, the balance will be upset and the temperature could be outside of the desired range.

To become familiar with the requirements of a properly designed steam tracing system, use the six design steps detailed below and on the following pages. Once comfortable with the steps and the information required, apply these steps to any size steam tracing project.

Step 1: Establish Design Parameters

Collect information relative to the following design parameters:

Application Information . . .

- · Pipe sizes
- · Pipe lengths
- Type and number of valves, pumps or other equipment
- Type and number of pipe supports

Expected Minimum Ambient Temperature . . . Generally, this number is obtained from weather data compiled for an area and is based on recorded historical data. There are times, however, when the minimum ambient will not be the outside air temperature. Examples include pipes and equipment located underground or inside buildings.

Desired Maintain Temperature . . . While the desired temperature might be a specific value, there will usually exist a temperature range where the product can effectively exist without any damage or upset. Any temperature extreme that could result in product or equipment damage should be noted to ensure this point is not reached.

Insulation Material and Thickness... While the type and thickness of insulation should be a variable in the design equation, there are times where a plant specification dictates a specific insulation standard. The selection tables in this design guide are based on calcium silicate insulation with thicknesses as shown in the various tables. If insulation materials other than calcium silicate are used, refer to the insulation correction factors shown in Table 4.2 or contact Thermon for design assistance.

Step 2: Select the Proper Thermon Steam Tracing Method For a steam tracing system to perform at optimum levels, choose the type of tracer that most closely meets the process design requirements using Table 2.1.

Table 2.1 Process Temperature vs. Tracer Type

Process Temperature Range	Tracer Type
Low 10°-38°C	Isolated
Medium-Low 39°-66°C	Isolated/Convection
Medium 67°-93°C	Convection/Conduction
Medium-High 94°-149°C	Conduction
High 150°-204°C	Conduction

Proper selection will avoid the effects of overheating and conserve energy. Where possible use only one tracer per process pipe (certain critical process lines may require a redundant heater). This will reduce the number of trap stations, isolation valves and fittings required while eliminating future maintenance on omitted materials.

After determining the tracer type, use Table 2.2 to establish the proper insulation thickness based on the temperature range to be maintained for a given nominal pipe size¹.

Table 2.2 Typical Insulation Thickness (mm)

Pipe Size		Te	emperature	Range	
mm	10°-38°C	39°-66°C	67°-93°C	94°-149°C	150°-204°C
40	25	25	25	25	25
50	25	25	25	25	25
80	25	25	25	25	25
100	25	40	40	40	40
150	25	40	40	40	50
200	40	40	40	50	50
250	40	40	50	50	50
300	40	40	50	50	50
350	40	40	50	50	64
400	40	50	50	50	64
450	40	50	50	64	64
500	50	50	50	64	64
600	50	50	50	64	64
750	50	50	50	64	75

To obtain more accurate design results and view what effects changing any of the variable inputs may have on the maintenance temperature, use Thermon's CompuTrace computeraided design and selection software program. Available on request from Thermon, this program provides accurate steam tracing performance data and load chart information that can be exported.

Step 3: Identify Base Maintain Temperature

Apply the fixed design factors established in Step 1 and the variable design factors selected in Step 2 to Tables 3.1 through 3.4 (see below for determining which table to use). Each table is divided based on tracer type with rows denoting the nominal pipe diameter and columns denoting steam pressure (temperature) and number of tracers. All of the tables are based on a minimum ambient temperature of -18°C and a wind speed of 11 m/s.

Process Temperature Maintenance (SI System)

Tracer Type	Steam Pressure	Table
Bare/BTS & Isolated	205, 308, 446 & 618 kPa	3.1
Bare/BTS & Isolated	791, 1136, 1480 & 1825 kPa	3.2
Heat Transfer Compound	205, 308, 446 & 618 kPa	3.3
Heat Transfer Compound	791, 1136, 1480 & 1825 kPa	3.4

Example . . . A process line requires steam tracing. The particulars for the line are:

Pipe diameter	250 mm
Desired maintain temperature	120°C
Insulation thickness	50 mm
Steam pressure (temperature)	791 kPa (170°C)
Minimum ambient/wind speed	18°C/11 m/s

Table 2.1 identifies the application as a "medium-high" temperature category and indicates the need for a conduction heater using heat transfer compound. Table 2.2 identifies that for a 250 mm diameter pipe maintaining 120°C, 50 mm thick insulation is needed. Based on these factors, use Table 3.4 to determine that one 10 mm or 12 mm diameter tube tracer with heat transfer compound will provide the desired maintain temperature.

Note . . .

Table is based on calcium silicate insulation oversized by one nominal pipe size to accommodate tracer. Refer to Table 4.2 for details on using other insulation materials.

Table 3.1 Process Temperature Maintenance (°C) IT, BT or BTS Tracers Ambient Temperature: -18°C, Wind: 11 m/s, Insulation: Calcium Silicate

		Nominal			t Tompord			Steam Pres

Notes . . . Tables 3.1 and 3.2 are based on calcium silicate insulation and give approximate values for cellular glass and perlite. Bare tracers are 12 mm O.D. tubing to provide for economical trap distances. Isolated tracers have 10 mm O.D. tubing. Use Table 4.1 to adjust for ambient temperatures other than -18°C.

For pipe temperatures below 27°C, consider using cellular glass or other insulation materials with a low moisture permeability.

Notes . . . Tables 3.3 and 3.4 are based on calcium silicate insulation and give approximate values for cellular glass and perlite. Tracers are 10 or 12 mm O.D. tubing with TFK-4 channel. Use Table 4.1 to adjust for ambient temperatures other than -18°C.

With HTC and channel, the contact area is the same for 10 or 12 mm O.D. tracers; therefore, the pipe temperature is the same for either tracer under like conditions.

Table 3.4 Process Temperature Maintenance (°C) HTC Tracers Ambient Temperature: -18°C, Wind: 11 m/s, Insulation: Calcium Silicate

Notes . . . Tables 3.3 and 3.4 are based on calcium silicate insulation and give approximate values for cellular glass and perlite. Tracers are 10 or 12 mm O.D. tubing with TFK-4 channel. Use Table 4.1 to adjust for ambient temperatures other than -18°C.

With HTC and channel, the contact area is the same for 10 or 12 mm O.D. tracers; therefore, the pipe temperature is the same for either tracer under like conditions.

Step 4: Apply Any Adjustment Factors

Ambient Temperature . . . If the minimum ambient will differ from the base level of -18°C established in Step 3, use Table 4.1 to apply an ambient correction factor. Multiply this coefficient by the difference in the ambient temperature and apply the result to the maintain temperature.

Insulation Materials . . . When insulation material other than calcium silicate is used, it will be necessary to apply an insulation correction factor. Use Table 4.2 to add or subtract the applicable value to the temperature maintenance value established in Step 3.

Note: If both the ambient temperature and the insulation material differ from the -18°C and calcium silicate base values established in Step 3, apply the ambient temperature change first followed by the insulation material change.

Examples . . . Using the information from the example on page 4:

- 1. What would be the effect on the pipe maintain temperature if the ambient temperature was -29°C instead of -18°C?
 - Locate the 250 mm diameter pipe size and 50 mm thick insulation rows under the one heat transfer compound (HTC) column to find a coefficient multiplier of 0.24. Multiply this value by the ambient temperature change: 0.24 x 11 = 2.6°C
 - Rounding 2.6 to the nearest whole value results in 3°C. Subtracting this number from the 120°C pipe temperature previously established results in a new maintain temperature of 117°C.
- 2. What would be the effect on the pipe maintain temperature if the thermal insulation was mineral wool? In the mineral wool column of Table 4.2, find the appropriate value for a 250 mm diameter line utilising one HTC tracer. Apply this value (12.8°C) to the 120°C maintain temperature established in Step 3 to obtain a new maintain temperature of 132.8°C.

 $\textbf{Note} \dots \textbf{Temperature adjustments are approximations only}.$

Step 5: Determine Steam Tracing Circuit Lengths

Steam tracing circuit lengths are frequently short due to the length or configuration of the traced piping and equipment. However, on long transfer lines, long circuit lengths are desirable to minimise the number of supply lines, valves and trapping stations required. Table 5.1 is based on 38 mm calcium silicate insulation, maximum pipe size groupings and variables for tracer size, conductance and low temperature limitations. Longer tracer runs may be possible based on a given pipe size, insulation type and thickness and allowable circuit pressure drop. Thermon's CompuTrace design and selection program should be used to obtain optimum circuit lengths based on application-specific design conditions.

The trapping distances found in Table 5.1 are based on tracer runs where the accumulated vertical tracer rise (AVTR) in metres does not exceed a given percentage of the inlet steam pressure as described below. It is important to consider the amount of vertical tracer rise when laying out steam tracing circuitry.

AVTR . . . The sum of all the increases in elevation is called the accumulated vertical tracer rise. A field-tested approach is to limit the AVTR (numerically) for any steam tracing circuit to a percentage of the inlet steam pressure. The approximate multiplier for pressure in kilopascals is 0.0066 to arrive at an allowable AVTR in metres (see Figure 5.1). Since kilopascals are usually given in absolute pressure, subtract 101 kPa from kPa absolute before using the 0.0066 multiplier. No adjustment in the trapping distance from the table is necessary if the above AVTR limit is adhered to and if the pressure drop is limited to 10% for computer-generated trapping distances. However, reductions in length are required for pressure losses due to bends, valves and fittings as shown in Table 5.2.

Notes . . .

- 1. Maximum pipe size 200 mm.
- For SLS-IT and DLS-IT, distance is based on maximum pipe size that can be held at 10°C or above.
- 3. Maximum pipe size 600 mm.
- 4. Maximum pipe size 750 mm.

mm	10 mm	12 mm	20 mm						
20	3	2							
25	4 to 8	3 to 5	2						
40	9 to 24	6 to 15	3 to 6						
50	25 to 48	16 to 30	7 to 13						

Recommended Header Size for Condensate Return Lines										
Header Size	Number of Tracers									
mm	10 mm	12 mm	20 mm							
25	Up to 8	Up to 5	Up to 2							
40	9 to 16	6 to 10	3 to 4							
50	17 to 40	11 to 25	5 to 11							

Step 6: Choose Options/Accessories

Thermon offers a variety of accessories to simplify the installation of isolated, convection and conduction tracers. Figure 6.1 identifies the typical accessories and their uses. For specific information on the accessories used with each product, refer to the Thermon product specification sheet for the tracer type/material.

Isolated Tracers . . . SafeTrace SLS-IT and DLS-IT tracers are attached to the process pipe with temperature-rated tape while the ends are protected from moisture penetration by self-vulcanising silicone rubber tape.

Convection Tracers . . . Bare tracers are typically installed with stainless steel banding. SafeTrace BTS tracers may be installed with the same tape used for SLS-IT and DLS-IT tracers. No end preparation is required for BTS tracers.

Conduction Tracers . . . Accessories to install Thermon heat transfer compounds include stainless steel banding, crimp seals, banding tools and galvanised steel channel.

Steam Supply and Condensate Return . . . Every steam tracing circuit requires a method to move the steam medium from the supply header to the tracer starting point and from the tracer end point to a condensate return manifold. SafeTrace SLS-IT and DLS-IT isolated tracers, because of their thermal retardant characteristics, can be installed continuously from the supply header, along the length of traced pipe and to the condensate return manifold.

When the tracers will be convection or conduction tracers, separate steam supply and condensate return lines are required. Thermon simplifies this requirement with ThermoTube™ preinsulated tubing. These copper or stainless steel tubes, available in numerous diameters, utilise nonhygroscopic glass fibre insulation, a heat reflective foil wrap and a weather-resistant outer covering. The preinsulated feature of

ThermoTube allows installation to be completed in one step as opposed to multiple steps required when using field-installed materials. For additional product information, refer to Thermon Form TSP0009U.

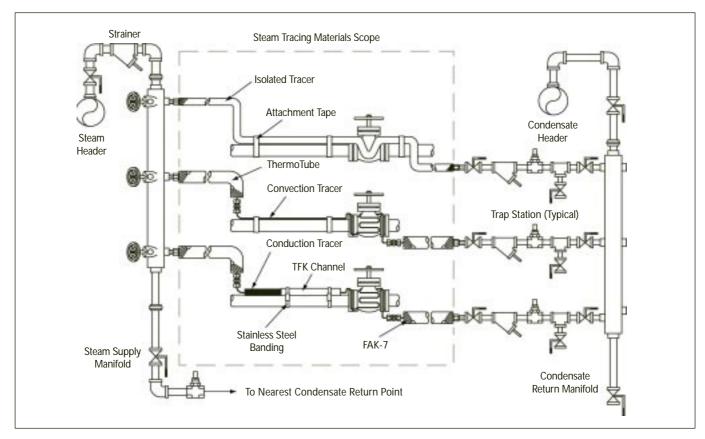

Figure 6.1 Typical Steam Tracing System

Basic Accessories . . .

Stainless Steel Banding...used to secure tracer, compound and channel to piping.

- T2SSB (12 mm wide, 0, 5 mm thick) for 10 mm and 12 mm O.D. tube tracers.
- T3SSB (12 mm wide, 0, 8 mm thick) for 20 mm or 25 mm O.D. tube and DN 20 or 25 pipe tracers.

C001...banding tool for applying tension to T2SSB or T3SSB banding.

1950A..crimping tool for T34PB-CR seals

T34PB-CR...crimp seals for fastening tensioned banding.

FT-1H...polyester fibre tape for circumferential banding of SafeTrace tracer to piping every 30 cm or as required by code or specification. Tape is 19 mm wide x 55 m long and has a maximum exposure temperature of 260°C.

FAK-7... end termination kit contains a roll of self-vulcanising silicone rubber tape and RTV sealant (sufficient materials to waterproof approximately six terminations). No heat gun or special tools are needed for installation. The FAK-7 has a maximum exposure temperature of 204°C.

TFK-4...galvanised steel channel covers heat transfer compound applied to 10 mm and 12 mm O.D. tube tracers.

TFK-7...galvanised steel channel covers heat transfer compound applied to 20 mm O.D. tube and DN 15 pipe tracers

TFK-9...galvanised steel channel covers heat transfer compound applied to 25 mm O.D. tube and DN 20 or 25 pipe tracers.

Design Optimisation Tips...

To ensure a properly operating steam tracing system and avoid commonly made mistakes, the following steam tracing recommendations have been compiled:

- 1. Select the tracer type that most closely meets the process design temperature requirements.
 - a. Conserves energy.
 - b. Avoids the effects of overheating.
- Use only one tracer per process pipe where possible to reduce the number of trap stations, isolation valves and fittings required. (Certain critical process lines may require a redundant heater.)
 - a. Reduces initial cost.
 - b. Eliminates maintenance of omitted materials.
- 3. Select a tracer that will meet the above conditions with existing steam pressure (up to 1825 kPa) where possible to decrease the use of pressure-reducing valves and increase the distance between traps, thus reducing the number of trap stations required. Isolated tracers can provide a low conductive heat path to reduce temperatures and conserve energy.
 - a. Reduces capital equipment cost.
 - b. Reduces installation costs.
 - c. Reduces system maintenance.
- 4. Use conduction tracers rather than steam-jacketed pipe where possible.
 - a. Significantly reduce material and labour costs.
 - b. Provide flexibility for maintenance.
 - c. Greatly reduce the number of trap stations required, forestalling future maintenance costs.
 - d. Can significantly reduce energy consumption.
- 5. Use flash steam from condensate or steam from exothermic processes where available.
 - a. Significantly reduces energy costs.
 - b. Low pressure steam provides more usable enthalpy, further increasing efficiency.
- 6. Use tubing rather than pipe for the tracer.
 - a. Reduces initial labour cost due to ease of installation.
 - b. Reduces number of fittings required, lowering the risk of steam leaks and future maintenance.
- Use appropriate trapping distance determinations rather than rule-of-thumb distances, which may not provide cost-effective lengths where long piping runs exist.
 - a. Reduce the number of trap stations and isolation valves and thus material and installation costs.
 - b. Eliminate maintenance of omitted materials.

- 8. Use preinsulated steam supply and condensate return lines.
 - a. Reduce labour and energy costs over field-installed and insulated lines.
 - b. Extruded outer jacket ensures that the thermal insulation is always weather-protected.
- 9. Use prefabricated steam supply and condensate collection manifolds for multiple tracing circuits.
 - a. Provide centralised location for steam distribution and condensate collection.
 - b. Minimise design time and installation costs.
 - c. Condensate collection manifolds with an internal siphon pipe prevent freezing and water hammer during start-up.
- 10. Use prefabricated trap stations.
 - a. Minimise installation and labour costs.
 - b. Standardised design reduces maintenance and spare parts.

Design Tips on Tracers . . .

For nearly every application, the following comments on steam tracer selection will apply:

- One BT or BTS bare convection tracer is the least expensive tracing system to install.
- Multiple BT or BTS tracers cannot be economically justified when one tracer with heat transfer compound (HTC) will suffice because of the additional steam supply connections and trap assemblies required. BT or BTS tracers may be doubled back where allowable pressure drops are not exceeded.
- Spiraled BT or BTS tracers on horizontal runs are not recommended because circumferential expansion reduces the heat transfer coefficient (by increasing the air gap between the tracer and the pipe) and the increased number of pockets requires more frequent trapping.
- Horizontal tracer runs are less labour-intensive to install and reduce water hammer.
- Isolated tracers (IT) provide energy savings in the range of 25% to 50% over bare convection tracers where they meet the process temperature requirements.
- In all cases, tracers that provide a measure of safety to aid compliance with applicable standards should be chosen.

Properties of Saturated Steam (SI Metric Units)

Pressure	Temp.	Heat Specific Pressure - Heat								Specific
